Can We Predict a Future Recession?

Team Data Detectives Project Overview:

Do GDP + T-Bill rates predict recession?

The generally accepted definition of a recession in the U.S., according to Forbes, is when GDP shrinks in two consecutive quarters. The National Bureau of Economic Research traditionally follows a more vague definition:

“A recession involves a significant decline in economic activity that is spread across the economy and lasts more than a few months.”

While GDP results typically define recession conditions, we want to know if ML can detect trends in quarterly results and predict a recession ahead of time.

Team Data Detectives sought to discover relationships between GDP, T-Bill rates, and economic health. Can machine learning predict a recession, with better than 75% accuracy, by analyzing historical data?

Data Sourcing

- Data sourced from U.S. Bureau of Economic Analysis (BEA)'s National Income and Product Accounts Metadata CSV files via the US Department of Economics.
 - Focused on last 65 years of GDP data, filtering for top 4 recession indicators since 1959.
 - Identified top 4 indicators: Personal Consumption Expenditures, Gross Private Domestic Investment, Net Exports of Goods and Services, Government Consumption Expenditures, and Gross Investment.
- Treasury rates for 65 years from Federal Reserve Economic Data (FRED) API

Data Model Implementation

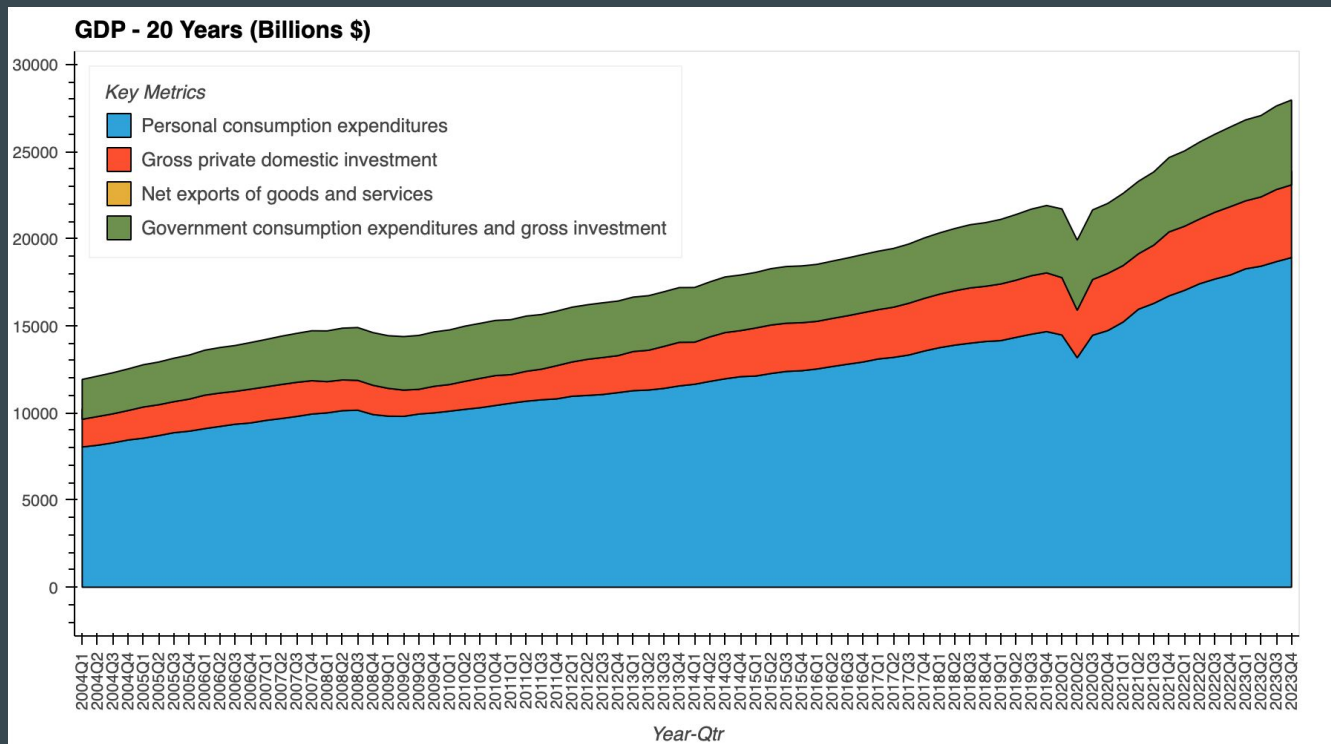

Logistic regression proved to be our most accurate model

- Comparing T-bill interest rates and GDP growth rate predicted recession with 98% accuracy

Other Methods Tested:

- Linear Regression
- Support Vector Regression
- Ensemble Model Learning

Findings: Gross Domestic Product (GDP)

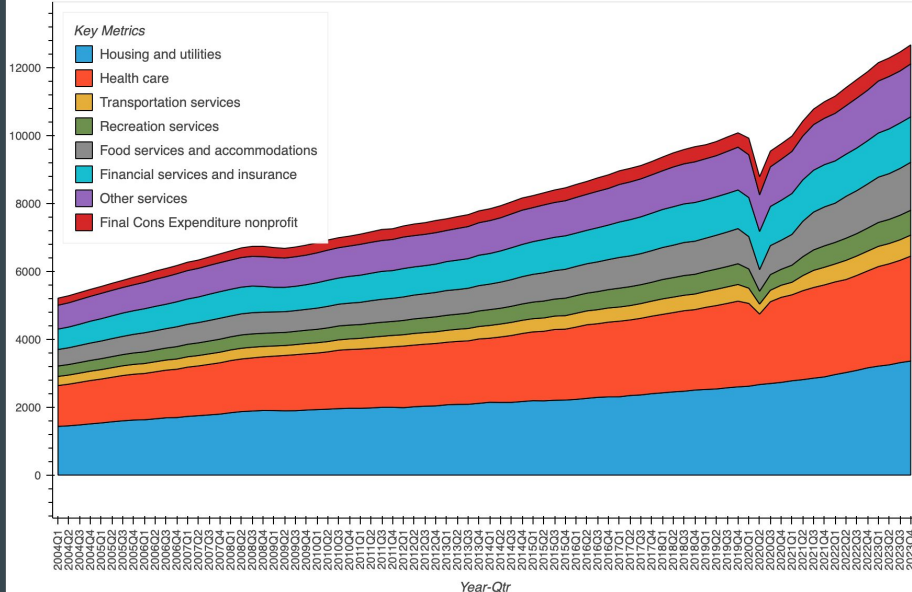

Findings: Personal Consumption Expenditures (PCE)

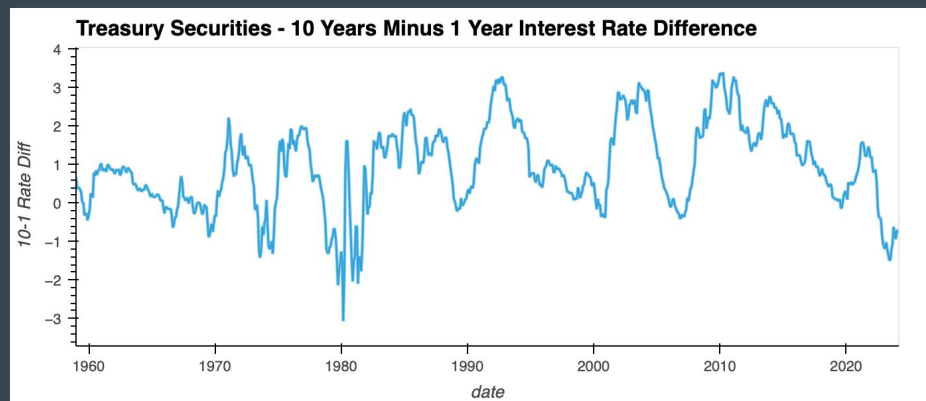

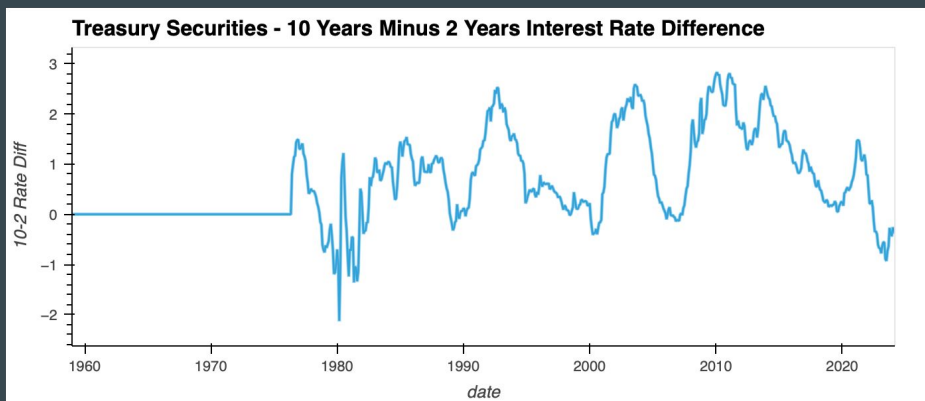

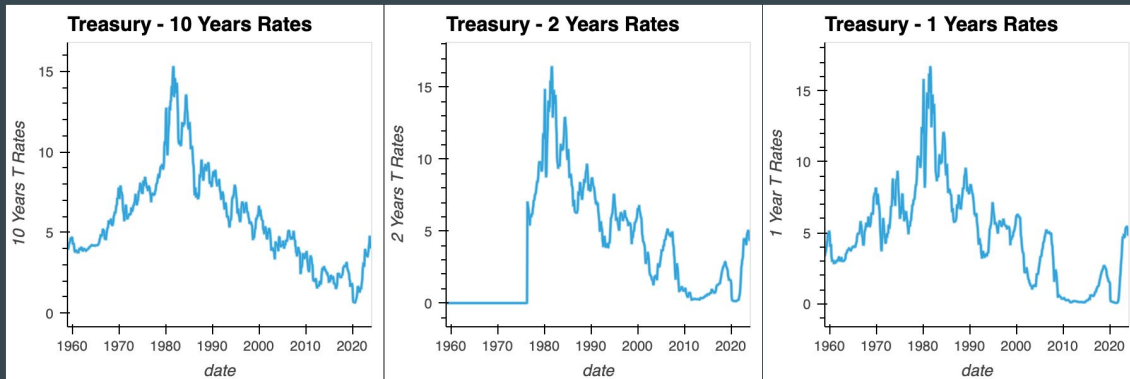

Personal consumption expenditures(**PCE**) - Services vs Goods - 20 Years(Billions \$)

PCE - Services - 20 Years(Billions \$)

Findings: Treasury

Data Model Optimization

- We developed data optimization in Python, working toward optimum ML performance
- Multiple models were tested, GDP and Treasury data were utilized
- Logistic regression ultimately achieved 98% accuracy

Conclusion

Can machine learning predict a future recession, with better than 75% accuracy, by analyzing historical GDP and Treasury data?

- After using multiple models to test the accuracy of this prediction, we concluded that there is indeed a way to use MLM with a high accuracy to predict a future recession.
- The precision and recall for 'Is_Recession' label 'False' are .98 and 1.00 respectively.
- The precision and recall for the 'Is_Recession' label 'True' are 1.0 and .50 respectively.
- The logistic regression model for predicting an economic recession based on difference in the interest rates of long term and short term treasuries is able to achieve an accuracy score of 98.07%
